DOI: <https://doi.org/10.66856/ijme.2026.8.1.8002>

Abstract

Applied research is frequently characterised as the "practical" aspect of knowledge production, aimed at addressing genuine issues in authentic contexts. However, choices made in professional settings are never solely technical. They are influenced by power dynamics, institutional frameworks, resource disparities, and conflicts regarding legitimacy. This article presents a journal-level critical sociology analysis of the impact of applied research on professional decision-making within management, technology, and service sectors, including tourism. Employing the theoretical frameworks of Bourdieu's forms of capital and field, world-systems theory, and institutional isomorphism, the paper contends that applied research serves as both a decision-support instrument and a vehicle of symbolic authority. Applied research can enhance decision-making by diminishing uncertainty, reinforcing learning cycles, and elucidating trade-offs; however, it may also perpetuate inequality through the disproportionate allocation of resources, the prevalence of specific languages and metrics, and the compulsion to emulate globally recognised models. The article suggests a unified framework that connects epistemic practice, institutional incentives, and global structures to clarify when applied research yields superior professional outcomes and when it devolves into a mere compliance ritual. It ends with useful ways to make methodological rigour, ethical accountability, and knowledge translation better while still respecting the differences between contexts.

Keywords: Applied research, evidence-based decision-making, professional practice, critical sociology, bourdieu capital, institutional isomorphism, world-systems theory, management research, technology governance, tourism innovation

Introduction

Why "Applied" Research Is Not Only About Application

Many organisations present "applied research" as a simple answer to a problem that keeps coming up: academic work can seem far away from real-world problems, and professionals have to make quick decisions with little time and incomplete information. People often talk about this tension as a difference between theory and practice. Applied research usually promises to take information from journals and use it to make tools, models, dashboards, guidelines, policies, and programs that help people make better decisions.

But this common way of looking at things hides a deeper truth. Decisions made in professional settings are influenced by social structures. What makes a decision "good" depends on your goals, incentives, values, and power dynamics. Who gets to say what the problem is, what evidence is valid, and what solutions can be put into action are all social questions. Applied research does not operate in a vacuum; it engages in a landscape of competition and collaboration, where participants possess varying resources and roles. This article, then, gives a more critical and theory-based account. It contends that applied research enhances decision-making not solely by generating data, but by transforming organisational definitions of legitimate knowledge and appropriate action. Applied research can help people make better decisions by teaching them and letting them evaluate their choices. However, it can also be a way for people to show their authority, protect their reputations, or copy "best practices" from other institutions without really fitting in with the local situation.

To develop this argument, the article uses three sociological frameworks that help explain the social life of applied knowledge

1. **Bourdieu's theory of fields and capital (economic, cultural, social, and symbolic capital):** useful for understanding how evidence becomes authority and why some actors' knowledge is treated as "more credible" than others.
2. **World-systems theory (core, semi-periphery, periphery):** useful for explaining why knowledge circulates unevenly across the global system and why some research agendas are considered universal while others are marginalized.
3. **Institutional isomorphism (coercive, normative, mimetic pressures):** useful for analyzing why organizations adopt similar research-driven practices (KPIs, audits, frameworks) sometimes for legitimacy rather than performance.

The analysis remains practical and relevant to decision-making in management, technology, and tourism, but it treats decision-making as a social process shaped by institutions and global inequality.

What Applied Research Really Means

1. Applied Research as a Mode of Knowledge Production

Applied research is typically defined as systematic inquiry oriented toward solving practical problems. Unlike basic research, which aims to expand general understanding, applied research seeks outcomes that can be implemented. However, applied research is not only "basic research with a practical topic." It is a different mode of knowledge production characterized by

- Contextual grounding (knowledge shaped by local conditions and constraints)
- Stakeholder involvement (decision-makers often influence research questions)
- Time sensitivity (results needed within operational or strategic cycles)
- Action orientation (outputs are recommendations, prototypes, policies, or interventions)

One important thing to remember is that applied research is a relationship, not just a method. It links academic logic (validity, rigour, peer review) with professional logic (timeliness, usefulness, and feasibility). This relationship is usually friendly, but it can also be tense.

2. Beyond the “Linear Model” of Knowledge Transfer

Many people think that knowledge moves in a straight line: first, theory is made, then it is used, and finally it is put into action. Applied research frequently operates in iterative cycles. Professionals identify an issue, researchers systematise it, evidence is collected, and the conclusions subsequently transform both theory and practice. This circular dynamic fits with the idea of learning organisations: organisations get better when they question their assumptions, think about the results, and change their routines. Applied research is a methodical approach to achieve this—when utilised with integrity.

3. Decision-Making in Organizations: Rationality, Limits, and Social Structure

3.1. Bounded Rationality and Real Decision Conditions

Professional decision-making transpires within the confines of bounded rationality. People who make decisions usually don't have all the information they need, enough time, or stable situations. Instead, they deal with incomplete signals, inaccurate predictions, and changing needs from stakeholders. Most of the time, decisions are "good enough," not the best. Applied research makes information better and options clearer. But this is only a small part of the whole picture.

3.2. Decisions as Social Negotiations

Many professional decisions are negotiated. A decision is not only a choice among options; it is also a negotiation over

- What the problem is (problem framing)
- Which outcomes matter (value priorities)
- Which metrics count (evaluation systems)
- Who is accountable (responsibility allocation)

Applied research influences these negotiations by offering evidence that can support certain frames and weaken others. This means applied research is never neutral in its effects. It can empower some actors and marginalize others.

Bourdieu: Applied Research as Capital and Power in Professional Fields

1. Fields, Positions, and the Struggle for Legitimate Knowledge

Bourdieu says that society is made up of fields, which are structured areas of competition where people fight over resources and legitimacy. Management, technology, and tourism are examples of professional fields where

businesses and professionals fight for clients, funding, talent, and recognition.

Applied research often becomes a strategic resource in these areas. It shows that you are serious, capable, and up-to-date. It can help a group say, "We base our decisions on facts, not opinions."

2. Forms of Capital in Applied Research

Economic capital: Funding for research, data systems, consultants, and evaluation teams. Organizations with more resources can build research departments, run pilots, and buy analytics tools.

Cultural capital: Skills, credentials, and technical literacy needed to interpret and produce research. Professionals trained in research methods have an advantage in shaping decisions.

Social capital: Networks of experts, partnerships, and institutional relationships. Access to reputable collaborators often determines which research is recognized and adopted.

Symbolic capital: Prestige and legitimacy, often appearing as credibility.

A report can carry symbolic capital when it is associated with respected authors, methods, or institutions.

Applied research improves decision-making partly because it increases cultural capital in organizations: it builds shared language, methods, and problem-solving capability. But it can also function as symbolic capital: a way to justify decisions already made or to strengthen authority without changing practice.

3. Symbolic Power: When Research Becomes “Official Truth”

Symbolic power is the ability to define what counts as reality in a field. In organizations, applied research can become a form of official truth that shapes budgets, promotions, and strategies. This can be positive when research genuinely improves decisions. But it becomes problematic when

- Data is selectively used to support preferred outcomes
- Metrics are treated as reality rather than imperfect indicators
- “Evidence-based” becomes a slogan rather than a practice

A critical approach therefore asks: evidence for whom, used by whom, and with what consequences?

World-Systems Theory: Global Inequality in Applied Knowledge

1. Knowledge Flows in a Core–Periphery System

World-systems theory highlights how the global system is structured by unequal exchange between core and periphery. This structure does not only apply to trade and labor; it also applies to knowledge.

In many sectors, “best practices” and influential research agendas often originate in core contexts and then travel outward. This can lead to policy transfer and management imitation that does not fit local realities.

Applied research can counter this by producing context-sensitive evidence in semi-peripheral and peripheral settings. But it can also reproduce dependency if local organizations only implement imported frameworks and treat local evidence as secondary.

2. Language, Metrics, and Global Legitimacy

A major mechanism of global inequality is that legitimacy is often tied to dominant languages, formats, and metrics. Research that is well-aligned with globally dominant styles is more likely to be recognized. This shapes applied research in professional environments: organizations may prefer models that look globally legitimate even if they are locally inefficient.

Applied research can improve decision-making when it resists this dynamic by prioritizing local context, stakeholder knowledge, and real outcomes rather than symbolic compliance.

Institutional Isomorphism: Why Organizations Copy “Evidence-Based” Practices

1. The Three Pressures Toward Similarity

Institutional isomorphism explains why organizations become similar over time, often by adopting the same frameworks, audits, and management systems.

- **Coercive isomorphism:** pressure from regulators, funders, or legal requirements (compliance, reporting, audits).
- **Normative isomorphism:** professional standards and shared educational training (industry norms, certifications).
- **Mimetic isomorphism:** imitation under uncertainty (copying what successful organizations do).

Applied research becomes part of this landscape. Organizations adopt research units, KPIs, dashboards, and evaluation frameworks because these signal legitimacy.

2. When Isomorphism Improves Decisions—and When It Does Not

Isomorphism can help people make better choices when shared standards really show what they know (like safety rules in engineering or evidence rules in healthcare). But it can also lead to ceremonial adoption, where processes are put in place to make things look modern instead of actually solving problems.

Applied research enhances decision-making when it is linked to practice, feedback, and results. It fails when it becomes a habit.

Mechanisms: Exactly How Applied Research Enhances Decision Quality

1. Better Problem Framing

Many poor decisions begin with poor problem framing. Applied research improves framing by

- Identifying root causes rather than symptoms
- Mapping stakeholder perspectives
- Clarifying system boundaries and constraints
- Making assumptions explicit

This is crucial in management and technology where problems are often multi-causal.

2. Evidence for Trade-Offs and Risk

Applied research improves decisions by quantifying trade-offs

- Cost vs. quality
- Speed vs. reliability
- Innovation vs. stability
- Growth vs. sustainability

It also improves risk governance by documenting uncertainty, testing scenarios, and identifying failure modes.

3. Learning Loops and Adaptation

Organizations improve when decisions generate learning. Applied research creates structured learning loops through

- Pilot studies and prototypes
- Monitoring and evaluation
- After-action reviews
- Iterative redesign

This is especially valuable in fast-changing environments like digital transformation.

4. Implementation Feasibility

Good decisions are implementable decisions. Applied research improves feasibility by

- Testing interventions in real settings
- Identifying operational bottlenecks
- Estimating resource requirements
- Integrating frontline feedback

Sector Illustrations: Management, Technology, and Tourism

1. Management: Evidence-Based Strategy and Organizational Learning

Applied research helps management make decisions by linking market data, the abilities of the organisation, and the realities of the employees. It makes governance better when it makes clear who is responsible, how well they are doing, and what ethical risks there are.

A sociological perspective, however, also indicates that strategy is political. Evidence can be employed to validate specific agendas. A grown-up applied research culture has openness, peer challenge, and multiple metrics instead of just one number that is "truth."

2. Technology: AI, Data, and Decision Governance

Technology decisions now shape employment, privacy, inequality, and organizational control. Applied research helps by assessing

- Adoption barriers and user behavior
- Bias and fairness risks
- Reliability under real conditions
- Human–technology interaction

From a critical perspective, technology research must ask: who benefits from automation, and who bears the risks?

3. Tourism: Innovation, Sustainability, and Service Quality

Tourism is highly sensitive to shocks, reputational signals, and changing consumer expectations. Applied research improves tourism decisions by analyzing

- Traveler preferences and segmentation
- Service quality drivers

- Environmental and community impacts
- Digital platforms and destination branding

Here institutional isomorphism is visible: destinations imitate global trends (smart tourism, sustainability labels). Applied research helps distinguish real sustainability from symbolic marketing.

Ethical Dimensions: Evidence, Responsibility, and Social Impact

Applied research influences decisions that affect people's livelihoods, privacy, safety, and dignity. Ethical applied research includes

- Informed stakeholder engagement
- Transparent methods and limitations
- Responsible use of indicators
- Attention to unintended consequences

In Bourdieu's terms, ethical applied research challenges symbolic domination by making power visible and by giving voice to those most affected by decisions.

Barriers to Effective Applied Research

1. Methodological Weakness and Over-Confidence

Applied research sometimes produces over-confident conclusions from weak designs. Common risks include

- Small or biased samples
- Confusing correlation with causation
- Over-reliance on proxy metrics
- Ignoring contextual factors

The solution is not "more complexity," but stronger transparency, triangulation, and cautious inference.

2. Incentives and Performative Evidence

Institutional pressures can turn applied research into performance. Organisations may collect data mainly to please funders or audits. When this happens, making decisions doesn't get any easier, and the paperwork grows.

3. Communication Gaps

When research is written in language that is hard to understand or comes too late, it doesn't help people make decisions. Applied research must adhere to decision timelines and convey information clearly while preserving nuance.

A Practical Framework for Bridging Theory and Practice

This article proposes an integrated framework where applied research improves decision-making when three conditions align

1. **Epistemic quality:** credible methods, transparent limitations, and appropriate interpretation
2. **Institutional alignment:** incentives that reward learning and impact, not only compliance
3. **Contextual justice:** attention to power, inclusion, and local realities in problem framing and implementation

Where one of these conditions is missing, applied research risks becoming symbolic rather than effective.

Conclusion

People often say that applied research is putting theory into practice. A critical sociology perspective reveals that it is a social process influenced by capital, institutions, and global inequalities. Applied research enhances professional decision-making by refining problem framing, elucidating trade-offs, facilitating implementation, and establishing feedback loops. If done poorly or mostly because of pressure to be legitimate, it can turn into a ritual that makes reports without changing anything. In fast-changing professional settings, the challenge is not just to "use research," but to create a culture where research is methodologically sound, socially aware, ethically responsible, and truly connected to practice. Bridging theory and practice is not solely a technical accomplishment; it constitutes an institutional and ethical endeavour.
